Abstract

Geoscience deals with all fields of natural science related to understanding past, current and future states of the Earth and the terrestrial bodies. Geoscience has many sub-disciplines that have strong roots in other sciences such as chemistry, physics, geography, biology and mathematics. Each sub-discipline generally works in isolation and is governed by different science unions, societies and associations. Datasets generated by each are diverse, complex and heterogeneous: few fully comply with the FAIR principles. Hence it is hard to integrate datasets both within and across each sub-discipline. To enable efficient integration of geoscience data to effectively contribute to societal grand challenges will require conformance to agreed international standards and compliance with FAIR.

The first attempt at international digital integration of data within one of these sub-disciplines was OneGeology, which in 2008 harmonised geological map data globally. More recently, OneGeochemistry is emerging as a fledgling effort to unify geochemical data across multiple sample types and analytical techniques in the geochemical domain. Geophysicists have not yet taken up the call for OneGeophysics but the potential is there.

Rather than developing standards completely within each sub-discipline, a more holistic approach is to leverage the Observation, Measurement and Samples (OMS) Standard (ISO 19156: 2023) and break down the standards and vocabularies required into modules based around the feature of interest, instrument, procedures, event, place, properties value, result, etc.

This presentation will highlight potential ways to use OMS to accelerate development and convergence of standards and vocabularies required to enable OneGeoscience to become a reality.

Geosciences Beyond Boundaries – Research, Society, Future

150th PGLA (BGR) Anniversary and 175th DGGV Anniversary

Berlin | 3 – 7 September 2023

OneGeoscience: Providing FAIR global access to all Geoscience data - are we there yet?

This talk is about Science and in increasing need to share data to enable new and better science

- 1) Set the scene: what is science?
- 2) Then and now - what is driving change?
- 3) OneGeology
- 4) OneGeophysics
- 5) OneGeochemistry
- 6) Geosciences beyond the boundaries
- 7) What are our priorities?

Setting the Scene: We are in a great time of change: What can we learn from history?

*Those who cannot remember
the past are condemned to
repeat it.*

George Santayana

Source: https://upload.wikimedia.org/wikipedia/commons/2/2a/George_Santayana.jpg

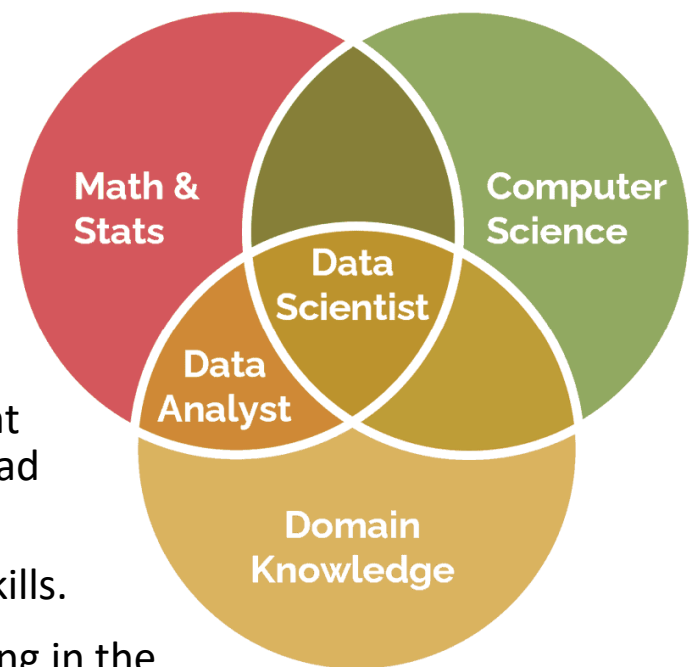

Who am I?

- I was born in the first half of the last century in the reign of King George VI.
- As an undergraduate in the late 1960's, computers were something in the postdoc/advanced research sections of the Physics department.
- The internet did not exist (neither did EXCEL): it was pen, paper and typewriter.
- There were no computer science departments: there was something called “Applied Mathematics”.
- University science courses taught science and nothing else.
- My formal training is in research science (geochemistry and mineral systems)
- Today, I would be called a “Data Scientist”

So what is a Data Scientist?

- In my beginnings there were no data scientists - there were nerdy scientists who cared about data, but there were no cheap tools to manage or store it.
- As the data deluge increased, computer experts were brought in to help researchers manage and process their data: they had no discipline knowledge.
- The majority of researchers had no data/computer science skills.
- Chaos ensued until it was recognised that there was something in the middle: researchers who understood data, and computer scientists with some discipline expertise - the data scientist was born.
- To me a data scientist is, and always sits, at the crossroads of science and computer science

Codd's 1970 Seminal Paper on Relational Database Management Systems

A Relational Model of Data for Large Shared Data Banks

E. F. Codd
IBM Research Laboratory, San Jose, California

Future users of large data banks must be protected from having to know how the data is organized in the machine (the internal representation). A prompting service which supplies such information is not a satisfactory solution. Activities of users at terminals and most application programs should remain unaffected when the internal representation of data is changed and even when some aspects of the external representation are changed. Changes in data representation will often be needed as a result of changes in query, update, and report traffic and natural growth in the types of stored information.

Existing noninferential, formatted data systems provide users with tree-structured files or slightly more general network models of the data. In Section 1, inadequacies of these models are discussed. A model based on n -ary relations, a normal form for data base relations, and the concept of a universal data sublanguage are introduced. In Section 2, certain operations on relations (other than logical inference) are discussed and applied to the problems of redundancy and consistency in the user's model.

KEY WORDS AND PHRASES: data bank, data base, data structure, data organization, hierarchies of data, networks of data, relations, derivability, redundancy, consistency, composition, join, retrieval language, predicate calculus, security, data integrity
CR CATEGORIES: 3.70, 3.73, 3.75, 4.20, 4.22, 4.29

1. Relational Model and Normal Form

1.1. INTRODUCTION

This paper is concerned with the application of elementary relation theory to systems which provide shared access to large banks of formatted data. Except for a paper by Childs [1], the principal application of relations to data systems has been to deductive question-answering systems. Levin and Maron [2] provide numerous references to work in this area.

In contrast, the problems treated here are those of data independence—the independence of application programs and terminal activities from growth in data types and changes in data representation—and certain kinds of data consistency which are expected to become troublesome

1. Future users of large data banks need to be protected from having to know how the data is organised in the machine (the internal representation).
2. Activities of users at terminals ... should remain unaffected when the internal representation of data is changed.
3. Changes in data representation will often be needed as a result of changes in query, update...and natural growth in the types of stored information.

Codd, E. F., 1970. A Relational Model of Data for Large Shared Data Banks. *Communications of the ACM* Volume 13 Issue 6, June 1970 pp 377–387 <https://doi.org/10.1145/362384.362685>

What is a scientist?

- A true scientist is one whose data and conclusions can be independently verified
- Therefore, input artefacts (samples, software, data, algorithms, etc) need to be transparent, open and accessible so we can validate the both the data and then assess the conclusions

https://upload.wikimedia.org/wikipedia/commons/thumb/3/3e/Einstein_1921_by_F_Schmutzer_-_restoration.jpg/1280px-Einstein_1921_by_F_Schmutzer_-_restoration.jpg

Then and now:
What are the greatest changes I have seen?

Geosciences Beyond Boundaries – Research, Society, Future

150th PGLA (BGR) Anniversary and 175th DGGV Anniversary

Berlin | 3 – 7 September 2023

Our science today needs to address societal needs and contribute to grand challenges for sustaining our planet

SUSTAINABLE DEVELOPMENT GOALS

<https://sdgs.un.org/goals>

To solve Global Grand Challenges, we need to collaborate internationally on data

Author lists on research publications show a shift towards multinational teams; fewer teams are composed entirely of researchers from one country.

Proportion of papers

■ Multinational ■ Domestic ■ Single author

Modern research papers increasingly result from International collaborations

©nature

Monastersky, R., and Van Noorden, R., 2019. 150 years of *Nature*: a data graphic charts our evolution. *Nature*, 575(7781):22-23. <https://doi.org/10.1038/d41586-019-03305>

In the 1980's & 1990's storage and memory were expensive

- In 1980 storage was ~\$1M per gigabyte: efficiency was key!
- Controlled vocabularies:
 - Were critical to efficient storage;
 - Kept the data clean: helped those geologists who could not spell (i.e., 90%!!!)
- Around the turn of the century, I joined the international GeoSciML project: worked on key vocabularies, including rock types.

What Does More Computational Power Mean to our Science?

2019 Version

Science is changing - it is now the 'Power of the Individual Observation'

- Through the semantic web we can now visualise millions of individual words (data points), not create visualisations of interpretations of millions of words (data points).
- It is now the 'Power of the Each Observation'.
- New science is being enabled because we can look at data at full resolution

Network diagram of 400 carbon-bearing minerals (colored circles).

The **MagnetoTellurics time series data** publication (**MTtsdp**) codes: <https://github.com/nci/MTtsdp>

Processing Levels	Name	Description
Packed Raw Data	Raw Time Series	Telemetry data streamed from site loggers
Level 0	Edited Time Series	Time ordered instrument recorded data (e.g., raw voltages, counts) at full resolution
Level 1	Transformed Time Series	Level 0 data that have been transformed (e.g., calibrated, resampled, rotated, had noisy data removed, filters applied).
Level 2	Derived frequency domain processed data	Geophysical parameters (e.g., impedance tensors) derived from frequency domain time series processing of Level 1 data
Level 3	Derived modelling inputs and outputs	Level 2 parameters converted into input files for modelling and inversion algorithms with outputs mapped onto space-time grids.

Rees, N., Evans, B., Heinson, G., Conway, D., Yang, R., Thiel, S., Robertson, K., Druken, K., Goleby, B., Wang, J., Wyborn, L. & Seillé, H., 2019. The Geosciences DeVL Experiment: new information generated from old magnetotelluric data of The University of Adelaide on the NCI High Performance Computing Platform, ASEG Extended Abstracts, 2019:1, 1-6, DOI: [10.1080/22020586.2019.12073015](https://doi.org/10.1080/22020586.2019.12073015)

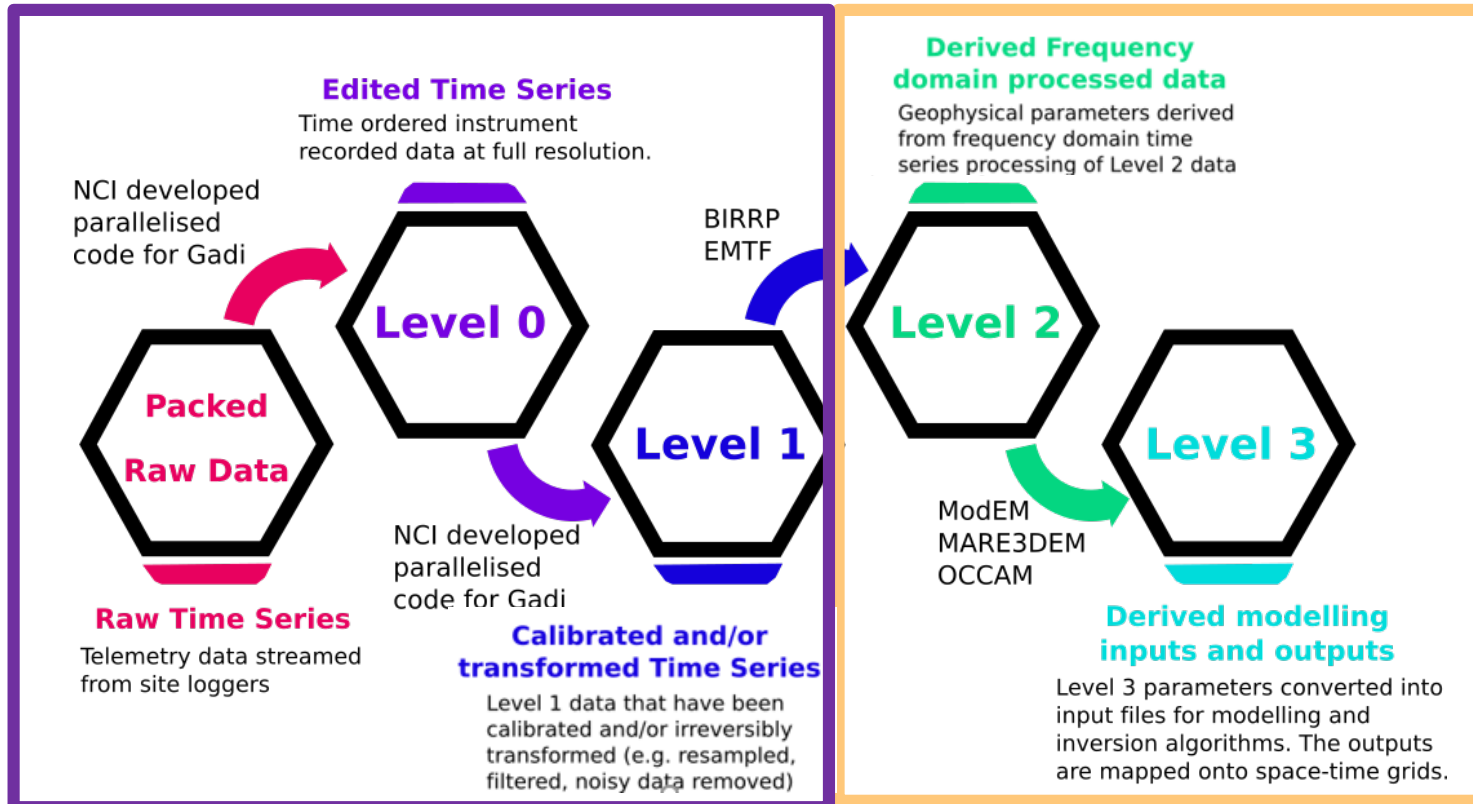

The greatest impact is the ability to use less processed data

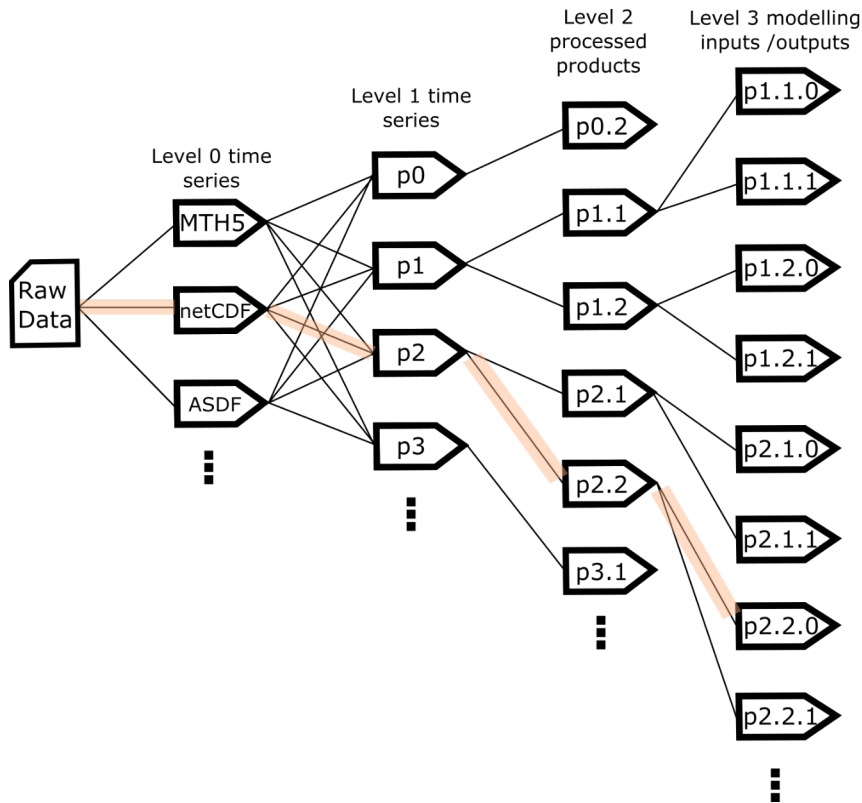

Transparently developing your own products

Focus of the 2030 Geophysics Project

What is normally accessible online

Transparent provenance between processing levels

Historically computationally based research involved an individual using their own data and processing it on their own private area, often using software they wrote or inherited from close collaborators.

Today's research is likely to be part of a large team (could be global) that will;

- use a subset of data from an external repository or multiple repositories
- Process the data on a public or private cloud or a large centralised supercomputer
- use a mixture of their own code, third party software, data services, libraries, stable global community codes

<https://doi.org/10.5281/zenodo.3332807>

<https://the-turing-way.netlify.app/reproducible-research/reproducible-research.html>

Why is it important?: same data for different purposes

Electrical conductivity is high here, e.g. rock types may be more conductive (such as shales), or may have mineralisation.

The Australian 2030 Geophysics Collection Project

- 2030 is an R&D project funded through a collaboration between AuScope, National Computational Infrastructure (NCI), Terrestrial Ecosystems Research Network (TERN) and the Australian Research Data Commons (ARDC)
- The project seeks to:
 - a. Make national-scale high-resolution geophysics datasets suitable for programmatic access in HPC environments;
 - b. Lay the foundations for more rapid data processing by 2030 next-generation scalable, data-intensive computation including Artificial Intelligence (AI)/Machine Learning (ML) and data assimilation.
- The project is NOT about building systems for the infrastructures and stakeholder requirements of today.
- Rather it is about positioning Australian geophysical data collections to be capable of taking advantage of next generation technologies and computational infrastructures by 2030.
- Project website: (<https://ardc.edu.au/project/2030-geophysics-collections/>)

What do we know about 2030 computing?

- High-end computational power will be at exascale
- Today's emerging collaborative platforms will continue to evolve as a mix of HPC and cloud
- Data volumes will be measured in Zettabytes (10^{21} bytes), which is about 10 times more than today
- **It will be mandatory for data discovery, accessibility, interoperability and reusability to be fully machine-to-machine as envisaged by the FAIR principles in 2016**

HPC has reduced processing times significantly

Testing Parallel I/O via NCI-geophys environment on the AusLAMP Musgraves Province time series data:
<https://doi.org/10.25914/58gr-1550>

Dataset of 93 MT stations	Serial I/O	MPI based Parallel I/O (96 cores)
Level 0: one MTH5/mt_metadata file for all stations	~ 14 hours	~ 35 minutes
Level 0: one MTH5/mt_metadata file per station	~ 5 hours 47 minutes	~ 4 minutes
Level 1: one MTH5/mt_metadata file per station	~ 49 minutes	~ 1.2 minutes
Level 2: one EDI file per station	~ 2 hours 30 minutes	~ 2 minutes

What are the opportunities of 2030 computing?

1. So often today's research is undertaken on pre-canned, analysis-ready datasets (ARD) that are tuned towards the highest common denominator as determined by the data owner/publisher.
1. By 2030:
 - Increased computational power co-located with fast-access storage systems will mean that geoscientists will be able to work on less processed data levels and then transparently develop their own derivative products.
 - Researchers will be able to see the quality of their algorithms more rapidly: there will be multiple versions of open source software used as researchers fine tune individual algorithms to suit their specific requirements.
 - We will be capable of more precise solutions and in hazards space and other relevant areas, analytics will be done in faster-than-real-time.

Our current world is imploding

In summary, we are living in a time of great change

1. We have more computation than we can use
 - *But is it necessary - I am happy with what I have?*
2. We are changing to data intensive computing that requires FAIR data and self describing formats
 - *But do we need to use data - can't we just use images?*
 - *Why do we need the actual data?*
3. We can move to working more and more on high resolution data sets
 - *Why - large, high resolution data files are too big for my online GIS system?*
4. Standards are changing to machine actionable
 - *So what - my software can't read the new standards, so I can't change*

The Head:

- Astronomy
- Climate
- High Energy
- Physics
- Genomics
- Geophysics

But either is

- Not Shared
- Not Reusable
- Not Interoperable

The Long Tail:

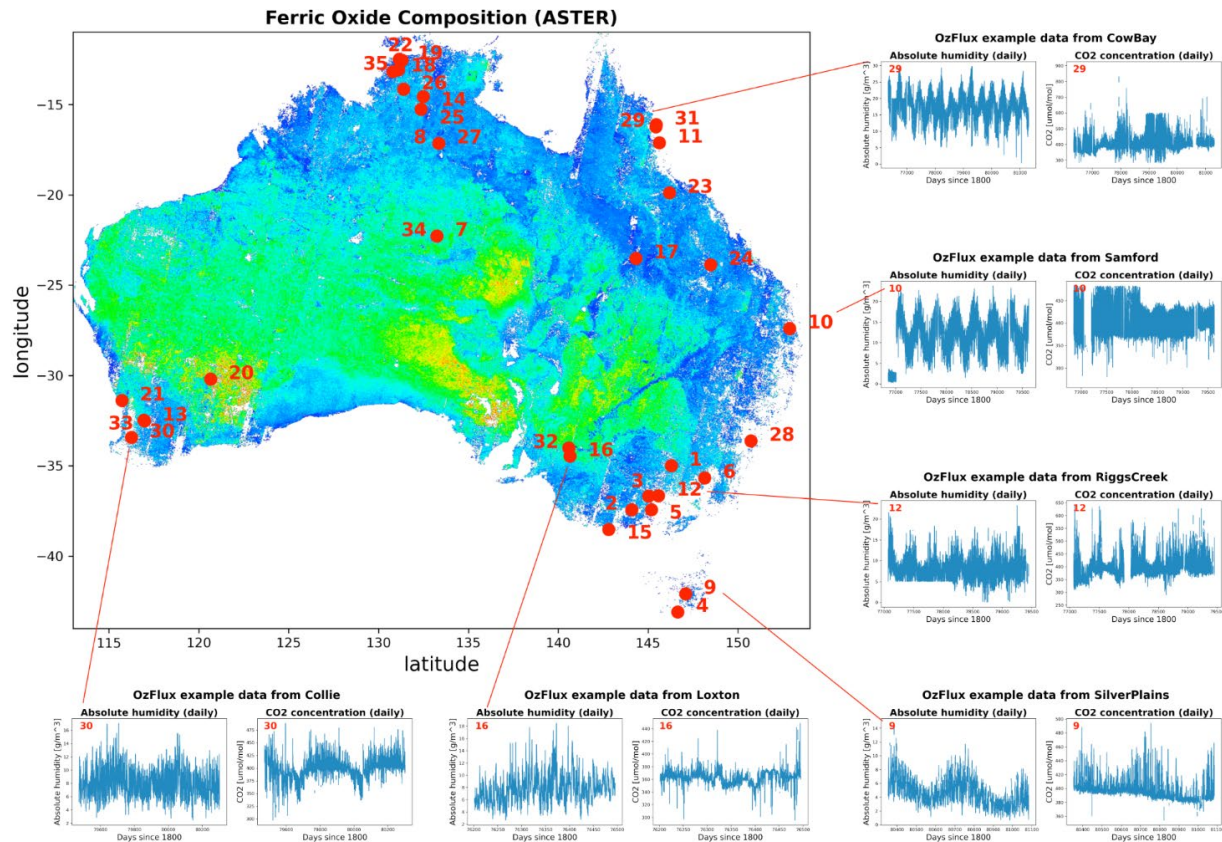

- Geochemistry
- Chemistry

Common Excuses for not sharing

- Often specialized
- Low volume
- Collected by many people
- Heterogeneous
 - In purpose (many disciplines)
 - In provenance (many methods)
- Fragmented data landscape
- Un-curated (on C drives)
- Hard to find & access
- Not persistent
- Difficult to integrate
- Not machine-readable

The power of point-located observations

OzFlux tower site locations (red dots) are plotted on the ASTER Ferric Oxide Composition of Australia layer. Time series data for CO₂ and absolute humidity are shown for six OzFlux tower sites. ASTER data were sourced from NCI's Gadi gdata file system and the OzFlux data were drawn from the TERN THREDDS Data Server.

Point located observational data are vital for accurate calibration of remotely sensed data

Geochron Workshop reports sponsored by EarthChem and EARTHTIME

Walker, Douglas J.; Condon, Daniel; Thompson, William; Renne, Paul; Koppers, Anthony; Hodges, Kip; Reiners, Peter; Stockli, Daniel; Schmitz, Mark; Bowring, Samuel; Gehrels, George

This report compilation describes the outcomes of a series of workshops sponsored by EarthChem and EARTHTIME. The goal of the workshops was to establish community requirements regarding data reporting and the approach employed for getting data into the database are used with the Geochron database. The reports are grouped by technique, and include:

Abstract

"Reporting and Interpretation of Geochronologic Data": Invitation for special papers in the Geological Society of America Bulletin

The science editors of the *Geological Society of America Bulletin* are encouraging a series of invited special papers to be published during the next 3+ years that highlight current best practices in the reporting and interpretation of geochronologic data and metadata.

The need for such reviews has become acute as the number of manuscripts submitted to *GSA Bulletin* (and other journals) whose conclusions are founded on radiometric dating of minerals, rocks, and organic materials has grown explosively during the past decade. Justification includes the following: (1) Many radiometric dating methods are in use, including some relatively new methods. (2) Data and metadata sets are commonly large and often contain dozens to thousands of isotopic measurements. (3) With increasing precision of many dating methods, the interpretation of large complex data sets is not always straightforward. It is becoming a challenge for many readers of *GSA Bulletin* to appreciate how a large set of isotopic dates is used to determine a geologically meaningful age for a rock or process. (4) Standardization of many methods has been greatly improved, but a plethora of standard values often requires re-calibration of published data sets.

The papers will be written by specialists, but the aim is that they will be presented in a form that is readily accessible to the broad readership of *GSA Bulletin*. Ideally, each paper would: (1) present a brief overview of the chronometer including the fundamental underlying assumptions and sources of uncertainty; (2) discuss what materials are most suited for analysis and how these are collected in the field and prepared in the laboratory; (3) address the limits on the age range of applicability; (4) review the principal applications; (5) recommend minimum requirements for data and metadata reporting about samples and the isotopic information derived from them with an eye toward archiving the data in a format that will be accessible for the foreseeable future; and (6) provide examples of the challenges in determining ages from complex sets of dates.

We hope to strengthen the role of *GSA Bulletin* in its function of archiving metadata that are of sufficient quality and completeness so that any potential future user has all the information needed to use it—or update it—as standards, decay constants, or production rates, interpretive strategies, etc., evolve.

We intend that these papers will become a valuable resource for authors who generate, organize, and interpret geochronologic data for publication, as well as for editors and associate editors who must evaluate the integrity of geochronologic data sets and the conclusions based upon them.

We seek papers that address these issues for the most widely used geo- and thermochronometers including:

1. U-Pb ID TIMS
2. In situ U-Pb laser ablation ICPMS and SIMS
 - a. U-Pb and La-Hf laser ablation split stream (LAAS)-MC-ICPMS
 7. Optical luminescence
 8. Radioisotopes
 9. Fission track
 10. Re-Os
 11. Other ionochron methods (Pb-Sr, Sm-Nd, etc.)
3. $^{40}\text{Ar}/^{39}\text{Ar}$ (and K-Ar)
4. U-series disequilibrium
6. Cosmogenic surface exposure methods
 - a. Noble gas methods (^{10}Be , ^{26}Al)
 - b. AMS-based methods (^{10}Be , ^{26}Al , ^{14}C)

Abstract

The LA-ICP-MS U-(Th)Pb geochronology international community has defined new standards for the determination of U-(Th)Pb ages. A new workflow defines the appropriate propagation of uncertainties for these data, identifying random and systematic components. Only data with uncertainties relating to random error should be used in weighted mean calculations of population ages; uncertainty components for systematic errors are propagated after this stage, preventing their erroneous reduction. Following this improved uncertainty propagation protocol, data can be compared at

The size of your community you share data with counts

- The growing need to share data, information and services across multiple disciplines and organisations
- This requires standards for machine readability
- Increasingly digital data collections need to be reused and repurposed by much broader communities
- The size of the community that you interoperate with is as large as the size of the community that uses your standard
- Where possible we need to converge on international standards

3-TIERED APPROACH TO VOCABULARIES

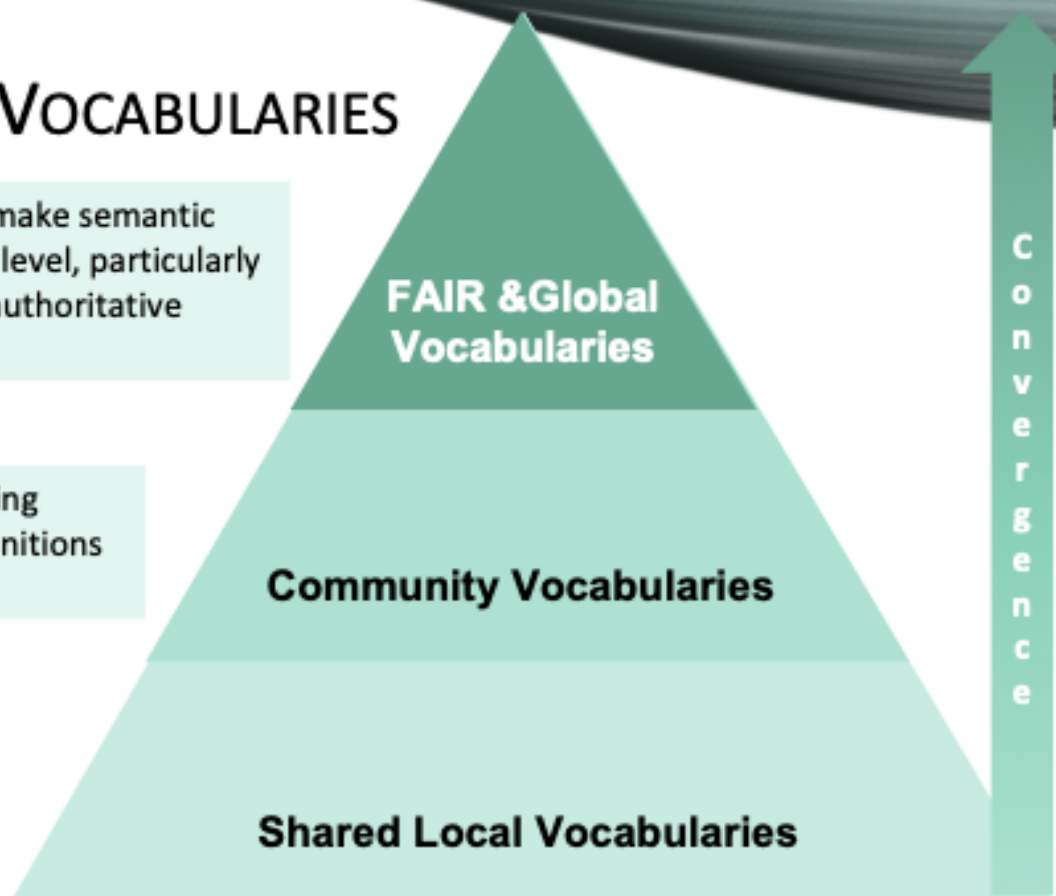

Raise awareness of groups harmonizing and make semantic resources FAIR-compliant at an international level, particularly those with endorsement from International authoritative groups (eg Scientific Unions/Societies).

Groups with similar topics to begin harmonizing across multiple locally-derived concepts/ definitions and publish these as community resources;

Data providers with locally defined vocabularies to make them available online and ensure each term has a persistent ID;

*Those who cannot remember
the past are condemned to
repeat it.*

George Santayana

Codd's 1970 Rules of Relational Database Management Systems (RDBMS)

1. Future users of large data banks need to be protected from having to know how the data is organised in the machine (the internal representation).
2. Activities of users at terminals ... should remain unaffected when the internal representation of data is changed.
3. Changes in data representation will often be needed as a result of changes in query, update...and natural growth in the types of stored information.

Codd, E. F, 1970. A Relational Model of Data for Large Shared Data Banks. Communications of the ACM Volume 13 Issue 6, June 1970 pp 377–387 <https://doi.org/10.1145/362384.362685>

A Relational Model of Data for Large Shared Data Banks

E. F. Codd
IBM Research Laboratory, San Jose, California

Future users of large data banks must be protected from having to know how the data is organized in the machine (the internal representation). A prompting service which supplies such information is not a satisfactory solution. Activities of users at terminals and most application programs should remain unaffected when the internal representation of data is changed and even when some aspects of the external representation are changed. Changes in data representation will often be needed as a result of changes in query, update, and report traffic and natural growth in the types of stored information.

Existing noninferential, formatted data systems provide users with tree-structured files or slightly more general network models of the data. In Section 1, inadequacies of these models are discussed. A model based on n -ary relations, a normal form for data base relations, and the concept of a universal data sublanguage are introduced. In Section 2, certain operations on relations (other than logical inference) are discussed and applied to the problems of redundancy and consistency in the user's model.

KEY WORDS AND PHRASES: data bank, data base, data structure, data organization, hierarchies of data, networks of data, relations, derivability, redundancy, consistency, composition, join, retrieval language, predicate calculus, security, data integrity
CR CATEGORIES: 3.70, 3.75, 3.75, 4.20, 4.22, 4.29

1. Relational Model and Normal Form

1.1. INTRODUCTION

This paper is concerned with the application of elementary relation theory to systems which provide shared access to large banks of formatted data. Except for a paper by Childs [1], the principal application of relations to data systems has been to deductive question-answering systems. Levein and Maron [2] provide numerous references to work in this area.

In contrast, the problems treated here are those of *data independence*—the independence of application programs and terminal activities from growth in data types and changes in data representation—and certain kinds of *data consistency* which are expected to become troublesome

1. We no longer have the gift of time.
2. When you publish a dataset with a paper, ask yourself how many other people are using your standards, formats and vocabularies - that will tell you the size of the community that can read and understand your data.
3. Although there is a the focus on distribution of images and derived products, we still need to find all the rawer forms of critical geoscience datasets and make less processed forms of these data more FAIR compliant and able to be aggregated into seamless national/global high-resolution datasets.
4. Ensure that whatever we do, it is always scalable to the future and can maximise benefits from new compute, data and software technologies as they come on line. Things will always change.
